Abstract
Background: Chronic obstructive pulmonary disease (COPD) is related to inflammation and obstruction of the lungs and airways. Protein arginine methyltransferase 5 (PRMT5) that promotes arginine methylation of histones is associated with inflammation of endothelial cell and is implicated in lung branching morphogenesis and progression of lung cancer. The mechanism of PRMT5 in inflammatory response of COPD was explored in this study.

Methods: Human bronchial epithelial cells, 16HBE, were treated with cigarette smoke extract for 24 h to establish cell model of COPD. Cell viability was examined by MTT assay. Western blot and reverse transcription-quantitative polymerase chain reaction (RT-qPCR) assays were used to explore expression of PRMT5. Expression of Interleukin (IL)-6, IL-8, tumor necrosis factor-α (TNF-α), and IL-1β were investigated by enzyme-linked immunosorbent assay.

Results: Cigarette smoke extract treatment induced cytotoxicity of 16HBE with reduced cell viability. PRMT5 was enhanced in cigarette smoke extract-induced 16HBE. Knockdown of PRMT5 increased cell viability of cigarette smoke extract-induced 16HBE, and attenuated cigarette smoke extract-induced increase of IL-6, IL-8, TNF-α, and IL-1β. Up-regulation of C-X-C Motif Chemokine 10 (CXCL10) in cigarette smoke extract-induced 16HBE was restored by knockdown of PRMT5. Over-expression of CXCL10 counteracted with the suppressive effect of PRMT5 silence on expression of IL-6, IL-8, TNF-α, and IL-1β. Moreover, PRMT5 silence-induced increase of cell viability in cigarette smoke extract-induced 16HBE was reversed by over-expression of CXCL10.

Conclusion: Knockdown of PRMT5 promoted cell viability of cigarette smoke extract-induced 16HBE, and reduced inflammation through down-regulation of CXCL10.

Introduction

Chronic obstructive pulmonary disease (COPD) is one of the most common respiratory diseases and is characterized by progressive and irreversible limitation of airflow. The most common pathological features of COPD are emphysema caused by small airway stenosis and rupture of the lung tissue that results in high morbidity and mortality. COPD is associated with exposure to harmful gases and particles that lead to abnormal inflammatory responses. Genetics and environment are the major factors for the etiology of COPD, and the most cases of COPD are caused by environmental factors, especially chronic smoking. Cigarette smoking and other inhaled substances trigger macrophages and epithelial cells to release large amounts of chemokines, and subsequently neutrophils, monocytes, and lymphocytes are recruited to the damaged tissues, such as peripheral airways and the lung parenchyma. Therefore, reducing exposure to risk factors, including smoking and exposure to second-hand smoke, is an effective way to prevent COPD.

Protein arginine methyltransferase (PRMT) family catalyzes arginine monomethylation, asymmetric, or symmetrical dimethylation modifications, involved in conserved and ubiquitous physiological processes. Regulation of PRMTs on immune cells is related to pulmonary disorders. PRMT5 modulates cell growth and transformation through catalyzation of omega-N\(^{-}\)-mono-methyl arginine and symmetric omega-N\(^{-}\), and N\(^{\alpha}\)-dimethyl arginine was shown to be associated with the progression of lung cancer. Cell metastasis of lung cancer was promoted by PRMT5. PRMT5 was also implicated in inflammatory diseases. For example, PRMT5 regulated differentiation and function of regulatory T cells (Tregs) during the development of ulcerative colitis, and suppressed synovial destruction and inflammation to attenuate rheumatoid arthritis. Previous study has shown that the messenger RNA (mRNA) expression of PRMT5 was enhanced in the lung tissue specimen of patients with COPD. However, the role and mechanism of PRMT5 in COPD remains elusive.

In this study, in vitro cell model of COPD was established in human bronchial epithelial cells (16HBE) through incubation with cigarette smoke extract. The effect of PRMT5 on inflammation of cigarette smoke extract-induced 16HBE, as well as the underlying mechanism, was then investigated.

Materials and methods

Cell culture and treatment and transfection

Human bronchial epithelial cells (16HBE) were obtained from ATCC (Manassas, VA, USA), and cultured in F12K medium containing 10% fetal bovine serum (Gibco, Rockville, MD, USA). Cigarette smoke extract was prepared from without filter cigarettes. Briefly, a negative pressure suction device was used to collect cigarette smoke extract from cigarettes without filters. The extract was then poured into a flask for shaking, the bacteria were removed, and the suspensions were collected through a 0.22-μm membrane filter. The extract was diluted in F12K medium containing 10% fetal bovine serum to obtain 0.5%, 1%, and 2% cigarette smoke extracts. The 16HBE was incubated with 0.5%, 1%, and 2% cigarette smoke extracts for 24h before function assays.

Cell viability assay

The 16HBE post-cigarette smoke extract was plated on a 96-well plate, and transfected with small interfering RNA (siRNA) targeting PRMT5 (si-PRMT5) or the negative control (si-NC) (YouBio, Changsha, China) by Lipofectamine 2000 (Invitrogen, Carlsbad, CA, USA) for 24h. pcDNA-CXCL10 and negative control (pcDNA) were constructed by YouBio, and cotransfected with si-PRMT5 or si-NC into 16HBE post-cigarette smoke extract by Lipofectamine 2000 (Invitrogen) for 24h. The 16HBE post-cigarette smoke extract with or without transfection was seeded on plate for another 24, 48, or 72h. Cells were incubated with MTT solution (Dojindo, Tokyo, Japan) for 4h, and dissolved with DMSO (dimethyl sulfoxide). Absorbance at 490nm was measured by microplate reader (Bio-Rad, Hercules, CA, USA).

Enzyme-linked-immunosorbent serologic assay (ELISA)

The 16HBE post-indicated treatment was lysed in radioluminoprecipitation assay lysis buffer (Beyotime, Shanghai, China) and centrifuged at 12000g for 1h to collect supernatants. Interleukin (IL)-6, IL-8, tumor necrosis factor-α (TNF-α), and IL-1β levels were determined by commercial kits (Nanjing Jiancheng Bioengineering Institute, Nanjing, China).

Reverse transcription-quantitative polymerase chain reaction (RT-qPCR)

The 16HBE was lysed by Trizol (Invitrogen) to collect RNAs. The RNAs were used to generate complementary DNAs (cDNA), and RT-qPCR analysis of PRMT5 was determined by SYBR Premix Ex Taq II (Takara, Tokyo, Japan). Glyceraldehyde 3-phosphate dehydrogenase (GAPDH) was used as an endogenous control, and the following primers were used: PRMT5 (forward primer: 5′-CCATGGAACAAAAAC-3′) and GAPDH (forward primer: 5′-GCCGCGCCGCCAACA-3′) and GAPDH (forward primer: 5′-CCATGGAACAAAAAC-3′) and reverse primer: 5′-TGCTGATGATCTTGAGGCTG-3′).

Western blotting assay

Proteins isolated from 16HBE were separated by SDS-PAGE, and transferred to polyvinylidene difluoride (PVDF) membranes (Millipore, Shanghai, China). The membranes were blocked in phosphate-buffered saline solution with a low-concentration detergent solution (PBST) with 5% non-fat milk, and incubated with primary and secondary antibodies, including anti-PRMT5 (1:2500; Abcam, Cambridge, UK), anti-CXCL10 (1:3000; Abcam), and anti-GAPDH (1:3500;
Cell signaling, Boston, MA, USA). ECL reagents (Roche, Shanghai, China) was used to detect protein signals, followed by incubation with horseradish peroxidase (HRP)-secondary antibody (1:5000; Abcam).

Statistical analysis

All experimental data were manifested as mean±standard deviation (SD). Differences between groups were analyzed by Student’s t-test or one-way analysis of variance. P<0.05 was considered as statistically significant.

Results

PRMT5 was up-regulated in cigarette smoke extract-induced 16HBE

In order to establish cell model of COPD, 16HBE was incubated with different concentrations of cigarette smoke extract for 24 h. Treatment with cigarette smoke extract reduced cell viability of 16HBE (Figure 1A). Both mRNA (Figure 1B) and protein (Figure 1C) expressions of PRMT5 were up-regulated in cigarette smoke extract-induced 16HBE, suggesting that PRMT5 might be involved in COPD.

Down-regulation of PRMT5 increased cell viability of cigarette smoke extract-induced 16HBE

Cigarette smoke extract-induced 16HBE was transfected with si-PRMT5 to investigate role of PRMT5 in COPD (Figure 2A). Result established that transfection with si-PRMT5 enhanced cell viability of cigarette smoke extract-induced 16HBE (Figure 2B), demonstrating the proliferative effect of PRMT5 silence on COPD.

Down-regulation of PRMT5 suppressed cigarette smoke extract-induced inflammation in 16HBE

Levels of IL-6, IL-8, TNF-α, and IL-1β were increased in 16HBE 24 h after treatment with 2% cigarette smoke extract (Figure 3). However, knockdown of PRMT5 decreased the levels of IL-6, IL-8, TNF-α, and IL-1β in cigarette smoke extract-induced 16HBE (Figure 3), indicating the anti-inflammatory effect of PRMT5 silence on COPD.

PRMT5 mediated cell viability and inflammation of cigarette smoke extract-induced 16HBE through regulation of CXCL10

The downstream target of PRMT5, CXCL10, was also up-regulated in cigarette smoke extract-induced 16HBE

Figure 1 PRMT5 was up-regulated in cigarette smoke extract-induced 16HBE. (A) Treatment with cigarette smoke extract reduced the cell viability of 16HBE. (B) Treatment with cigarette smoke extract enhanced the mRNA expression of PRMT5 in 16HBE. (C) Treatment with cigarette smoke extract enhanced the protein expression of PRMT5 in 16HBE. * ** vs. control, P<0.05, P<0.01.

Figure 2 Down-regulation of PRMT5 increased cell viability of cigarette smoke extract-induced 16HBE. (A) Transfection with si-PRMT5 reduced the protein expression of PRMT5 in cigarette smoke extract-induced 16HBE. (B) Transfection with si-PRMT5 promoted cell viability of cigarette smoke extract-induced 16HBE. * ** vs. 2% CSE+si-NC, P<0.05, P<0.01.
Degradation of PRMT6 aggravated cigarette smoke extract-induced lung epithelial cell apoptosis and inflammation. Considering that PRMT5 was associated with lung branching morphogenesis and enhanced in the lung tissue specimen of patients with COPD, the regulatory role of PRMT5 on COPD was investigated in this study.

Cigarette smoke extract has been shown to induce apoptosis and inflammation of bronchial epithelial cells. Therefore, cigarette smoke extract-induced 16HBE was widely used as cell model of COPD. In this study, cigarette smoke extract induced decrease in the cell viability of 16HBE. In line with the previous study that PRMT5 was up-regulated in the lung tissue specimen of patients with COPD, PRMT5 was also enhanced in 16HBE after treatment with cigarette smoke extract. Moreover, knockdown of PRMT5 increased cell viability of cigarette smoke extract-induced 16HBE, suggesting the proliferative effect of PRMT5 silence on COPD. However, the role of PRMT5 on cigarette smoke extract-induced apoptosis of 16HBE should be investigated in the future research.

Cigarette smoke promotes activation of peripheral blood leukocytes and release of proinflammatory mediators resulting in tissue damage in pulmonary tissues during COPD progression. Suppression of inflammatory responses was considered to be a potential therapeutic strategy for the prevention of COPD. Proinflammatory mediators (IL-1β, IL-6, and TNF-α) were up-regulated in cigarette smoke extract-induced 16HBE. IL-6, IL-8, TNF-α, and IL-1β levels in this study were found to be up-regulated in cigarette smoke extract-induced 16HBE, suggesting the proliferative effect of PRMT5 silence on COPD. However, the role of PRMT5 on cigarette smoke extract-induced apoptosis of 16HBE should be investigated in the future research.

Metabolism of arginine was altered in patients with COPD, and dysregulated expression or activity of PRMTs was implicated in the pathogenesis of COPD. For example, cigarette smoke extract induced suppression of PRMT6 to promote airway epithelial cell death. Degradation of PRMT6 aggravated cigarette smoke extract-induced lung epithelial cell apoptosis and inflammation. Considering that PRMT5 was associated with lung branching morphogenesis and enhanced in the lung tissue specimen of patients with COPD, the regulatory role of PRMT5 on COPD was investigated in this study.

Conclusion

In summary, PRMT5 and the downstream target were differentially expressed in cigarette smoke extract-induced 16HBE, and knockdown of PRMT5 suppressed inflammatory response in cigarette smoke extract-induced 16HBE through down-regulation of CXCL10. This study provided a novel target for clinical treatment of COPD. However, the protective effect of PRMT5–CXCL10 against COPD must be confirmed in murine emphysema model induced by cigarette smoke extract.
