Abstract
Objective: The aim of the present study is to investigate the effects of auraptene on inflammation and apoptosis of pneumonia model and uncover the mechanism.
Methods: WI-38 cells were treated with lipopolysaccharide (LPS) to construct a pneumonia model. Cell counting kit-8 assay, enzyme-linked-immunosorbent serologic assay, and quantitative polymerase chain reaction assay were conducted to confirm the effects of auraptene on the viability and inflammation of WI-38 cells. Flow cytometry (FCM) and immunoblot assays were conducted to detect the effects of auraptene on the apoptosis of WI-38 cells. Immunoblot assay was performed to confirm the mechanism.
Results: We found that auraptene stimulated cell viability in WI-38 cells upon LPS treatment. Auraptene also inhibited cellular inflammation. Furthermore, auraptene inhibited cell apoptosis of WI-38 cells upon LPS treatment. Mechanically, auraptene inhibited the nuclear factor **NF-κB** signaling pathway, thereby suppressing the pneumonia.
Conclusion: Auraptene alleviates inflammatory injury and cell apoptosis in pneumonia, thus has the potential to act as a pneumonia drug.

Introduction
Pneumonia is a global illness with high morbidity and mortality, causing approximately 1.4 million child deaths annually. The incidence of pediatric pneumonia is high, with many complications and poor prognosis. There is still a lack of effective treatment for pediatric pneumonia, leading to an urgent requirement of the related research and developing an effective regimen. Pneumonia is a serious disease featured by a combination of local and systemic complications. Therefore, it is vital to explore pathogenesis and therapeutic target for treating pneumonia.

Auraptene is isolated from many edible fruits and vegetables. Auraptene has multiple therapeutic
properties, such as anti-diabetic, antigenic, antibacterial, antifungal, anti-genotoxic, anti-leishmania, anti-inflammatory, anti-Helicobacter, and immunomodulatory. Auraptene has demonstrated anti-inflammatory and neuroprotective effects in the brains of inflammatory models injected with lipopolysaccharide (LPS). Auraptene has alleviated gastritis by reducing production of proinflammatory mediator. Auraptene has shown anti-inflammatory characteristics by suppressing the production of inflammatory proteins that mediated association between fat cells and macrophages. Auraptene has regulated human platelet activation and prevented arterial thrombosis in mice by inhibiting nuclear factor kappa B (NF-κB) axis. However, the role of auraptene in pediatric pneumonia has remained unclear.

NF-κB is involved in immune and inflammatory responses and has induced the levels of downstream inflammatory cytokines that mediate inflammatory response in pathological actions. TNF-α and TNF receptors are expressed on several immune cells and have regulated the survival and activation of T cells. One of the main causes of lung infection is the presence of LPS that effectively stimulates immune cells. Therefore, the NF-κB pathway may serve as a target for treating pneumonia.

In the present study, we proposed to elucidate the effect of auraptene on pneumonia. We constructed LPS-treated WI-38 cell model. Our results revealed that auraptene alleviated inflammatory injury and cell apoptosis in pneumonia. Therefore, auraptene has the potential to act as a pneumonia drug.

Materials and methods

Cell culture

This study was approved by the Ethics Committee of the Affiliated Hospital of Xiangnan University. The human bronchial epithelial cell line WI-38 were obtained from American Type Culture Collection (ATCC) and cultured in Dulbecco's modified eagle medium (DMEM) supplemented with 10% fetal bovine serum (FBS) in a 5% CO2 humidified atmosphere at 37°C. Cells were treated with 5-μg/mL LPS and auraptene (Sigma, St. Louis, MO, US) for 24 h to construct the cell model.

Cell viability

WI-38 cells were plated into 96-well plates. Cell viability was assessed by adding cell counting kit-8 (CCK-8) solution (Beyotime, Shanghai, China). Cells were incubated with CCK-8 solution for 4 h and optical density (OD) was observed through the measurement of OD450.

Enzyme-linked-immunosorbent serologic assay (ELISA)

The concentrations of TNF-α, IL-1β, and IL-6 in cell lysates were measured with ELISA kit (Beyotime, Beijing, China) following manufacturer’s protocol.

Real-Time Polymerase chain reaction (RT-PCR)

Total cellular RNA was extracted with TRIzol reagents (Thermo Fisher, MA, US). Total RNA was reverse-transcribed into complementary DNA (cDNA) using M-MLV reverse transcriptase (Promega, Madison, WI, US). The relative expression of target genes were determined by RT-PCR. The following primers were used: TNF-α: GGTTGCTATGTCTAGCCCTT, GCCATAGAAGCTGATGAGGGGAG; interleukin 1β: IL-1β: ACAAGGAGAAGAAAGTAAATGAC, GCTGTAAGTGGGCTTAT; IL-6: AGACAGCCACTACCC, TTCTGCAGTGCTTCTT; and glyceraldehyde 3-phosphate dehydrogenase (GAPDH): AGAAGGTGGGGCTCATTTC, AGGGCCATCCACAGTCTTC.

Western blot analysis

Proteins were extracted using radioimmunoprecipitation assay (RIPA) buffer (Beyotime). Then, the samples were collected and separated by 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE), and transferred on polyvinylidene fluoride (PVDF) membranes. After blocked with 5% fat-free milk, PVDF membranes were incubated with primary antibodies, including Bax (1:1000; ab32503; Abcam, Cambridge, UK), Bcl-2 (1:1000; ab182858; Abcam), p-p65 (1:1000; ab76302; Abcam), p65 (1:1000; ab32536; Abcam), p-IκBα (1:1000; ab133462; Abcam), IκBα (nuclear factor of kappa light polypeptide gene enhancer in B-cells inhibitor, alpha) (1:1000; ab237777; Abcam), and β-actin (1:3000; ab8226; Abcam) for 1 h. The membranes were incubated with secondary antibodies for 1 h. Specific proteins were visualized with enhanced chemiluminescence (ECL) kit (Thermo Fisher).

Cell apoptosis assay

Cell apoptosis kit was bought from Beyotime. Cells were fixed with 70% ethanol for 2 h. Subsequently, cells were stained with propidium iodide (PI) and fluorescein isothiocyanate (FITC) Annexin V at 4°C, and the apoptosis rate was measured. The cell apoptosis was assessed using FACs Calibur flow cytometer and analyzed by CellQuest Pro 5.1 (BD Biosciences, NJ, US).

Statistics

The GraphPad 8.0 software was used for statistical analysis. Data were represented as mean ± SD. The unpaired Student’s t-test was used to determine statistical significance between two groups. P < 0.05 was considered statistically significant.

Results

Auraptene stimulated the cell viability in LPS-stimulated WI-38 cells

The structure of auraptene is shown in Figure 1A. LPS-stimulated WI-38 cells were constructed as a pneumonia
Wang Y et al.

The addition of auraptene improved cell viability (Figure 1C). Therefore, auraptene stimulated the cell viability of WI-38 cells upon LPS treatment.

**Auraptene inhibited LPS-induced cell inflammation**

To assess inflammatory gene levels in LPS-stimulated WI-38 cells, the messenger RNA (mRNA) levels of IL-6, IL-1β, and TNF-α were discovered. LPS increased the mRNA levels of these genes through quantitative PCR (qPCR; Figure 2A). We further found that auraptene administration relieved cellular inflammation by reducing the levels of these cytokines (Figure 2A). Consistently, the protein secretion of these factors after auraptene treatment showed the same results (Figure 2B). Therefore, auraptene inhibited LPS-stimulated cell inflammation.

**Auraptene inhibited LPS-induced cell apoptosis in LPS-induced WI-38 cells**

We discovered the effects of auraptene on LPS-induced WI-38 cell apoptosis. The cell apoptosis was observed by flow cytometry (FCM) assay. Induction of LPS in WI-38 cells increased cell apoptosis (Figure 3A). Auraptene treatment significantly reduced the percentage of apoptotic cells (Figure 3A). In addition, the expression levels of Bax and Bcl-2 were detected in WI-38 cells. LPS treatment obviously enhanced Bax levels and reduced Bcl-2 levels (Figure 3B). However, alterations in Bax and Bcl-2 were reversed by auraptene treatment (Figure 3B). Therefore, auraptene inhibited LPS-induced cell apoptosis in WI-38 cells upon LPS treatment.

Auraptene alleviates pneumonia

A variety of drugs have achieved good results in the preclinical treatment of pneumonia, but it is still difficult to meet the current clinical requirements. In the present study, we constructed a pneumonia LPS cell model, and found that auraptene could suppress the progression of pneumonia at cellular levels. We conceived that auraptene has the potential to act as a pneumonia drug. In addition, exercise is a rehabilitation strategy with anti-inflammatory effects and could be a good plan to treat pneumonia.

Inflammation, a self-protective response of vascular living tissue to injury, is closely associated with neurodegenerative and cardiovascular diseases. NF-κB signaling pathway was involved in the LPS-stimulated inflammation model. We observed the possible association of auraptene and NF-κB signaling pathway. LPS treatment increased the levels of p65 and IκBα phosphorylation in WI-38 cells, which were the indicators of this pathway, compared to control (Figure 4). However, auraptene reduced the p65 and IκBα phosphorylation levels in WI-38 cells upon LPS treatment (Figure 4). Thus, auraptene restrained NF-κB activation in WI-38 cells upon LPS treatment.

Discussion

Pneumonia is an inflammation of the lungs caused by pathogens invading the alveoli. Pneumonia can occur at all ages, but is more common in children aged <2 years. For pediatric pneumonia, there is still a lack of drugs, leading to urgent requirement of related research and development work. The treatment of pneumonia should focus on inhibiting excessive inflammatory response and alleviating cell apoptosis. A variety of drugs have achieved good results in the preclinical treatment of pneumonia, but it is still difficult to meet the current clinical requirements.

In the present study, we constructed a pneumonia LPS cell model, and found that auraptene could suppress the progression of pneumonia at cellular levels. We conceived that auraptene has the potential to act as a pneumonia drug. In addition, exercise is a rehabilitation strategy with anti-inflammatory effects and could be a good plan to treat pneumonia.

Inflammation, a self-protective response of vascular living tissue to injury, is closely associated with neurodegenerative and cardiovascular diseases. By performing a series of assays, such as CCK-8, FCM, ELISA, and Immunoblot, we found that auraptene alleviated LPS-induced inflammation and apoptosis of WI-38 cells. Auraptene, an active secondary metabolite, is primarily isolated from the plants of the Rutaceae family. Auraptene is effective in treating several disorders, such as keloids and pain. Auraptene possesses numerous pharmacological properties, such as anti-hypertensive and anti-cancer.
Therefore, Auroraaptene has the potential to act as a drug for the treatment of pneumonia.
